Two New Species of *Aconitum* (Ranunculaceae) from Xizang

WANG Wen-Tsai

(State Key Laboratory of Systematic and Evolutionary Botany, Institute of Botany,
Chinese Academy of Sciences, Beijing 100093, China)

Abstract: Two species of the genus *Aconitum* (Ranunculaceae), *A. novoaxillare* and *A. basitruncatum*, are described as new from Xizang Autonomous Region, China. The diagnostic differences between them and their allies are given.

Key words: Ranunculaceae; *Aconitum*; New species; Xizang

Aconitum novoaxillare W. T. Wang, sp. nov.

Fig. 1.

Species nova haec est arcte affinis *Aconito sino-axillari* W. T. Wang, quod foliorum laminis 3-partitis utrinque glabris, pedicellis inferne puberulis, bracteolis multo majoribus foliaceis 1.5–1.8 cm longis 1.2–1.7 cm latis, petalis minoribus 8 mm longis, eorum unguibus 3.5 mm longis facile differt.

Tubers carrot-shaped, 2.5–4 cm long, at apex 0.9–1.8 cm across. Stem ca. 95 cm tall, near base 7–9 mm across, proximally sparsely spreading-puberulous, distally sparsely retrorse-puberulous, simple. Leaves petiolate; blades thinly papery, pentagonal, 2.5–9 cm long, 5–11 cm broad, at base cordate, 3-sect, central segment rhombic, at apex long acuminate, 3-fid or subpinnatifid, with triangular-linear lobes, lateral segments obliquely flabellate, unequally 2-parted; surfaces adaxially and abaxially

sparsely appressed-puberulous; petioles 0.7–10 cm long, glabrous. Flowers borne singly in the axils of 2–4 apical leaves; pedicels 2–4 cm long, distally spreading-puberulous, below the middle or above base 2-bracteolate; bracteoles filiform, 2–4 mm long, ca. 0.12 mm across, glabrous. Sepals blue, abaxially glabrous; upper sepal navicular, ca. 1.4 cm high, 7 mm broad, shortly beaked and clawed, lower margin ca. 1.6 cm long, above concave; lateral sepals suboblate, ca. 1.4 cm long, 1.3 cm broad, adaxially sparsely puberulous; lower sepals not seen. Petals ca. 1.7 cm long, glabrous; claws ca. 1.5 cm long; limbs ca. 6.5 mm long, 2 mm broad; lips 2 mm long, slightly reflexed, at apex dilated and emarginate; spurs incurved, 1.2–1.5 mm long. Stamens glabrous; filaments 6–7 mm long, above filiform, elsewhere winged; anthers suborbicular or oblate, 0.5–0.8 mm in diam. Carpels 3, ca. 5 mm long, gla-

brous, with ovaries slightly longer than styles.

China. Xizang Autonomous Region: Chayu County, Ridong, from Qimazhala to Xizha, alt. 3 800 m, under *Abies* forest on slope, fls. blue, 26 Sept. 1982, Qinghai-Xizang Exped. 10718 (**holotype** & isotype, PE).

This species is closely related to *Aconitum sino-axillare* W. T. Wang, but differs in its 3-sect puberulous leaf blades, distally puberulous pedicels, much smaller filiform bracteoles, and larger petals which are 1.7 cm long and with claws 1.5 cm long. In *A. sinoaxillare*, the leaf blades are 3-parted and

glabrous, the pedicels are proximally puberulous, the bracteoles are much larger, foliaceous, 1.5–1.8 cm long, 1.2–1.7 cm broad, and the petals are very small, only 8 mm long, with claws only 3.5 mm

long (Wang and Hsiao, 1965).

***Aconitum basitruncatum* W. T. Wang, sp. nov.**

Species nova haec est affinis *Aconito kongboensi* Lauener, quod foliorum laminis basi profunde cordatis usque ad basin 3-sectis, sepalo supero majore 2–2.5 cm alto conspicue rostrato, petalis sparse hirtellis distinguitur.

Tubers unknown. Stems 1–1.5 m tall, near base ca. 8 mm across, retrorsely appressed-puberulous. Leaves petiolate; blades coriaceous, subpentagonal, ca. 5 cm long, 8 cm broad, at base subtruncate, 3-parted to 2–7 mm above base, central partition rhombic, 3-parted or 3-fid, the secondary lobes with 3–5 triangular, narrowly triangular or linear lobules, lateral partitions obliquely flabellate, unequally 2-parted, upper lobe similar to the central partition, but smaller, lower lobe unequally 2-parted too; surfaces adaxially sparsely appressed-puberulous, abaxially on nerves densely appressed-puberulous; petioles up to 9 cm long. Panicles ca. 50 cm long; lower bracts foliaceous, upper bracts 3-parted with linear lobes, or undivided, linear; axis with pedicels densely appressed-puberulous; pedicels 1.5–5 cm long, near the middle 2-bracteolate; bracteoles shortly petiolate or sessile, broadly rhombic, 7–10 mm long, 4–9 mm broad, 3-fid or 3-lobed, or undivided, long elliptic, 5–7 mm long, 2–4 mm broad. Sepals white, abaxially puberulous; upper sepal galeate, ca. 1.8 cm high, not beaked, lower margin ca. 1.3 cm long, slightly concave; lateral sepals slightly unequal in size, narrowly obovate or long elliptic, 1.2–1.3 cm long, 4–6 mm broad.

Petals glabrous; claws 1.3–1.6 cm long; limbs 3–4 mm long; lips 1.2–3 mm long, towards apex slightly dilated, at apex 2-lobulate or undivided; spurs incurved, 1.2–2 mm long, straight or slightly circinate. Stamens glabrous; filaments filiform, 4–5 mm long, below the middle winged, edentate; anthers subquadrate, ca. 0.8 mm broad. Carpels 3 (4), 4–4.5 mm long, glabrous.

China. Xizang Autonomous Region: Linzhi County, near Wuzhang, alt. 3200 m, in bush by river, fls. white, 25 Sept. 1983, Exped. from Xizang Institute of Biology 4025 (**holotype**, PE).

This species is related to *Aconitum kongboense* Lauener, but differs in its leaf blades subtruncate at base and deeply 3-parted nearly to the base, upper sepal smaller, not beaked, and glabrous petals. In *A. kongboense*, the leaf blades are deeply cordate at base and 3-sect to the base, the upper sepal is larger, 2–2.5 cm high and conspicuously beaked, and the petals are sparsely hirtellous (Lauener, 1963).
